What *Beamtime* adds

Numerical experiment tracking, made for **people and agents** working together.

FEATURE	USUALLY	WITH BEAMTIME
Testable hypotheses *say what you expect, then check it*	Hypotheses hide in your head, a doc, or your agent's chat history.	**Proposals**, **experiments**, **notes** and **verdicts** in one place; predictions checked for you.
People and agents *working on one shared record*	Runs sit on a hosted server; agents reach them through an API.	Agents work on the run files, local or remote, with **fast, compact MCP** answers.
Notes and memory *written together, shown in the UI*	Notes and reports drift apart from the runs and the predictions.	Notes record **verdicts** next to the data; a shared **memory** keeps the big picture.
Views you control *reusable blocks, no coding bottleneck*	Dashboards clicked together per project, hard to reuse or share.	Agents build **any view** from **reusable blocks**; a good view serves every new experiment.
Plain files you own *no server, no database, no account*	Data locked in a hosted service, a database or binary event files.	Every run is a plain folder you can read, search and version. **Nothing to host.**
Built for clusters *simulations and training jobs alike*	Jobs need network to upload, or offline runs are synced by hand.	See cluster runs from your laptop over **ssh**; compute nodes need **no internet**.

The research cycle
what Beamtime keeps, experiment after experiment
